

# Package: glm2 (via r-universe)

September 2, 2024

**Type** Package

**Title** Fitting Generalized Linear Models

**Version** 1.2.1

**Depends** R (>= 3.2.0), stats

**Description** Fits generalized linear models using the same model specification as glm in the stats package, but with a modified default fitting method that provides greater stability for models that may fail to converge using glm.

**License** GPL (>= 2)

**LazyData** true

**NeedsCompilation** no

**Author** Ian Marschner [aut] (using code from glm and glm.fit in the stats package), Mark W. Donoghoe [cre, ctb]

**Maintainer** Mark W. Donoghoe <markdonoghoe@gmail.com>

**Date/Publication** 2018-08-11 04:50:19 UTC

**Repository** <https://mdonoghoe.r-universe.dev>

**RemoteUrl** <https://github.com/cran/glm2>

**RemoteRef** HEAD

**RemoteSha** 0cf934151b2c680f90dcab40cb5520637bc7e7ac

glm2-package

*Fitting Generalized Linear Models*

---

## Description

Fits generalized linear models using the same model specification as `glm` in the **stats** package, but with a modified default fitting method. The method provides greater stability for models that may fail to converge using `glm`.

## Details

Package: glm2  
Type: Package  
Version: 1.2.1  
License: GPL (>=2)  
LazyData: true

There are two functions in the package, `glm2` and `glm.fit2`. The `glm2` function fits generalized linear models using the same model specification as `glm` in the **stats** package. It is identical to `glm` except for minor modifications to change the default fitting method. The `glm.fit2` function provides the default fitting method for `glm2`. It is identical to `glm.fit` in the **stats** package, except for modifications to the computational method that provide more stable convergence. Normally only `glm2` would be called directly, although like `glm.fit`, `glm.fit2` can be called directly. It can also be passed to `glm` as an alternative fitting method, using the `method` argument. See Marschner (2011) for a discussion of the need for a modified fitting method.

## Author(s)

Ian Marschner (using code from `glm` and `glm.fit` in the **stats** package)

Maintainer: Mark W. Donoghoe <markdonoghoe@gmail.com>

crabs

*Horseshoe Crab Data*

---

### Description

This data set is derived from Agresti (2007, Table 3.2, pp.76-77). It gives 4 variables for each of 173 female horseshoe crabs. Also provided are two random samples of the data with replacement, which are useful for illustrating the convergence properties of `glm` and `glm2`.

### Usage

```
data(crabs)
```

### Format

A data frame with 173 observations on the following 6 variables:

Satellites number of male partners in addition to the female's primary partner

Width width of the female in centimeters

Dark a binary factor indicating whether the female has dark coloring (yes or no)

GoodSpine a binary factor indicating whether the female has good spine condition (yes or no)

Rep1 a random sample with replacement from 1:173

Rep2 a second random sample with replacement from 1:173

### Details

The variables `Dark` and `GoodSpine` are derived from the raw data. In the notation of Table 3.2 of Agresti (2007), `Dark = yes` corresponds to  $C > 3$  and `GoodSpine = yes` corresponds to  $S < 3$ . The two random samples `Rep1` and `Rep2` can be used to provide random samples with replacement from the full data set. These two random samples are useful for illustrating the convergence properties of `glm` and `glm2`; see examples in the help documentation for `glm2`.

### References

## Description

glm.fit2 is identical to glm.fit in the **stats** package, except for a modification to the computational method that provides improved convergence properties. It is the default fitting method for glm2 and can also be used as an alternative fitting method for glm, instead of the default method glm.fit.

## Usage

```
glm.fit2(x, y, weights = rep(1, nobs), start = NULL,
         etastart = NULL, mustart = NULL, offset = rep(0, nobs),
         family = gaussian(), control = list(), intercept = TRUE,
         singular.ok = TRUE)
```

## Arguments

x	as for <a href="#">glm.fit</a>
y	as for <a href="#">glm.fit</a>
weights	as for <a href="#">glm.fit</a>
start	as for <a href="#">glm.fit</a>
etastart	as for <a href="#">glm.fit</a>
mustart	as for <a href="#">glm.fit</a>
offset	as for <a href="#">glm.fit</a>
family	as for <a href="#">glm.fit</a>
control	as for <a href="#">glm.fit</a>
intercept	as for <a href="#">glm.fit</a>
singular.ok	as for <a href="#">glm.fit</a>

## Details

glm.fit2 is a modified version of glm.fit in the **stats** package. The computational method in glm.fit2 uses a stricter form of step-halving to deal with numerical instability in the iteratively reweighted least squares algorithm. Whereas glm.fit uses step-halving to correct divergence and parameter space violations, glm.fit2 additionally uses step-halving to force the model deviance to decrease at each iteration, which improves the convergence properties. Like glm.fit, glm.fit2 usually would not be called directly. Instead, it is called by glm2 as the default fitting method. Like glm.fit, it is possible to call glm.fit2 directly if the response vector and design matrix have already been calculated, in which case it may be more efficient than calling glm2. It can also be passed to glm in the **stats** package, using the method argument, providing an alternative to the default fitting method glm.fit. See Marschner (2011) for a discussion of the need for a modified fitting method.

**Value**

The value returned by `glm.fit2` has exactly the same documentation as the value returned by `glm.fit`.

**Author(s)**

`glm.fit2` uses the code from `glm.fit`, whose authors are listed in the help documentation for the **stats** package. Modifications to this code were made by Ian Marschner.

[glm.fit](#)

**Examples**

```
library(glm2)

#--- logistic regression null model -----#
# (intercept estimate = log(0.75/0.25) = 1.098612)

y <- c(1,1,1,0)
x <- rep(1,4)

#--- divergence of glm.fit to infinite estimate ---#
fit1 <- glm.fit(x,y, family=binomial(link="logit"),start=-1.81)
fit2 <- glm.fit2(x,y, family=binomial(link="logit"),start=-1.81)
print.noquote(c(fit1$coef,fit2$coef))
```

---

glm2

*Fitting Generalized Linear Models*

---

**Description**

Fits generalized linear models using the same model specification as `glm` in the **stats** package, but with a modified default fitting method. The method provides greater stability for models that may fail to converge using `glm`.

**Usage**

```
glm2(formula, family = gaussian, data, weights, subset, na.action,
      start = NULL, etastart, mustart, offset, control = list(...),
      model = TRUE, method = "glm.fit2", x = FALSE, y = TRUE,
      singular.ok = TRUE, contrasts = NULL, ...)
```

**Arguments**

formula	as for <a href="#">glm</a>
family	as for <a href="#">glm</a>
data	as for <a href="#">glm</a>
weights	as for <a href="#">glm</a>
subset	as for <a href="#">glm</a>
na.action	as for <a href="#">glm</a>
start	as for <a href="#">glm</a>
etastart	as for <a href="#">glm</a>
mustart	as for <a href="#">glm</a>
offset	as for <a href="#">glm</a>
control	as for <a href="#">glm</a> except by default control is passed to <code>glm.fit2</code> instead of <code>glm.fit</code>
model	as for <a href="#">glm</a>
method	the method used in fitting the model. The default method " <code>glm.fit2</code> " uses iteratively reweighted least squares with modified step-halving that forces the deviance to decrease at each iteration; see help documentation for <code>glm.fit2</code> . As in <a href="#">glm</a> , the alternative method " <code>model.frame</code> " returns the model frame and does no fitting.
x	as for <a href="#">glm</a>
y	as for <a href="#">glm</a>
singular.ok	as for <a href="#">glm</a> . NB this is ignored (and defaults to TRUE) for R versions < 3.5.0.
contrasts	as for <a href="#">glm</a>
...	as for <a href="#">glm</a>

**Details**

`glm2` is a modified version of `glm` in the **stats** package. It fits generalized linear models using the same model specification as `glm`. It is identical to `glm` except for minor modifications to change the default fitting method. The default method uses a stricter form of step-halving to force the deviance to decrease at each iteration and is implemented in `glm.fit2`. Like `glm`, user-supplied fitting functions can be used with `glm2` by passing a function or a character string naming a function to the `method` argument. See Marschner (2011) for a discussion of the need for a modified fitting method.

**Value**

The value returned by `glm2` has exactly the same documentation as the value returned by `glm`, except for:

`method`                    the name of the fitter function used, which by default is "`glm.fit2`".

**Author(s)**

`glm2` uses the code from `glm`, whose authors are listed in the help documentation for the **stats** package. Modifications to this code were made by Ian Marschner.

family = poisson(link="identity"), start = rep(1,4),
control = glm.control(trace=TRUE))

noquote(c("deviances: ",fit1$dev,fit2$dev))
noquote(c("converged: ",fit1$conv,fit2$conv))

```

---

heart

*Heart Attack Data*

---

## Description

This data set is a cross-tabulation of data on 16949 individuals who experienced a heart attack (ASSENT-2 Investigators, 1999). There are 4 categorical factors each at 3 levels, together with the number of patients and the number of deaths for each observed combination of the factors. This data set is useful for illustrating the convergence properties of `glm` and `glm2`.

## Usage

```
data(heart)
```

## Format

A data frame with 74 observations on the following 6 variables.

Deaths number of deaths

Patients number of patients

AgeGroup categorization of the age of the patients  
Severity severity of the heart attack  
Delay categorization of the time from heart attack to treatment  
Region geographical region in which the patients were treated

### Details

The variable AgeGroup groups the age of the patients as follows: 1 = <65 years, 2 = 65-75 years, 3 = >75 years. The variable Delay groups the time from heart attack onset to treatment as follows: 1 = <2 hours, 2 = 2-4 hours, 3 = >4 hours. The variable Severity denotes the severity of the heart attack using the Killip class: 1 = least severe (class I), 2 = middle severity (class II), 3 = most severe (class III or IV). The variable Region provides the geographical region in which the patients were treated: 1 = Western countries, 2 = Latin America, 3 = Eastern Europe. This data set is useful for illustrating the convergence properties of glm and glm2; see examples in the help documentation for glm2.
